Hydroxyapatite (HAP) nanoparticles have been extensively studied for their potential applications in regenerative medicine. However, the surface of HAP nanoparticles has been shown to possess poor biocompatibility, in particular, poor in vitro toxicity to human cells, and the inflammatory response to HAP nanoparticles is still unclear. To solve the issue, we tried to determine in vivo toxicity of HAP nanoparticles to mice, as well as in vitro leukocyte-endothelial cell interaction. We first prepared HAP nanoparticles with sizes ranging from 40 to 210 nm. HAP nanoparticles showed no apparent cytotoxicity to mouse monocytes, nor did they affect the level of IL-6, MCP-1, or other cytokines in mouse blood plasma. In an in vitro study, HAP nanoparticles with different sizes were co-cultured with human leukocytes, and we found that leukocyte-endothelial cell interaction was minimal between leukocytes and endothelial cells in the absence of HAP nanoparticles. However, HAP nanoparticles were observed to significantly disrupt the integrity of endothelial cells and to increase the number of leukocytes that had adhered to the endothelial cells. These results suggest that HAP 82157476af
